

05 – Power BI Data Modeling & Transformation

Overview

Power BI was used not only for visualization but also for robust data modeling and transformation to support accurate analytics.

Multi-Select Field Handling

Multi-select fields were transformed using:

- Split Column by Delimiter
- Unpivot Columns

This approach enabled one-to-many relationships through bridge tables.

Bridge Tables

- Bridge_Concentration
- Bridge_Request

These tables support accurate filtering and aggregation.

Unique Identifier Standardization

The internal unique identifier was standardized using:

- Trim
- Clean
- Lowercase

This ensured consistency across tables and prevented broken relationships.

Dimension Tables

Dimension tables were created from unique values in bridge tables to enable scalable filtering and analysis.

Outcome

The data model supports flexible slicing, accurate metrics, and reliable dashboard performance.
